#### **Abstract**

The recent tensions on the measured value of the Hubble constant between CMB and astrophisical observations, has triggered the need of new methods for its determination. In view of this, an effort has been done by H0LiCoW to use the gravitational lensing of quasars as a probe for H0. This type of measurement requires a long term monitoring of lensed quasars (of the order of years). Since big telescopes have to deal with many observational requests, it is difficult to have a constant monitoring over the years, therefore this task can be achieved more easily by small/medium size telescopes. However, the number of lensed quasars with multiple images that can be resolved by these telescopes drops drastically. Here we present a method to deal with non resolved lensed quasars. This method has also the advantage of being less dependent on the microlensing effect of the lens galaxy.

#### I. Introduction

In the last years, the precision of the Planck [cita] experiment, whose task was to analyse the Cosmic Microwave Background (CMB) anisotropies, has allowed to fully test our standard cosmological model  $\Lambda$ CDM which assumes the existence of Dark Energy ( $\Lambda$ ) and Cold Dark Matter (CDM). In particular, in addition to the minimal 6 parameters describing  $\Lambda$ CDM, the CMB anisotropies allow to indirectly constrain other parameters, such as the current expansion rate of the Universe,  $H_0$ .

#### II. Methods

Maecenas sed ultricies felis. Sed imperdiet dictum arcu a egestas.

- Donec dolor arcu, rutrum id molestie in, viverra sed diam
- Curabitur feugiat
- turpis sed auctor facilisis
- arcu eros accumsan lorem, at posuere mi diam sit amet tortor
- Fusce fermentum, mi sit amet euismod rutrum
- \*A thank you or further information

- sem lorem molestie diam, iaculis aliquet sapien tortor non nisi
- Pellentesque bibendum pretium aliquet
